Why so slow on hard disk drive?

Problem I: in the original Unix File System, blocks were too small (512 bytes)

- File index too large
- Require more indirect blocks
- Transfer rate low (get one block at time)

Problem 2: unorganized freelist

- · Consecutive file blocks not close together pay seek cost for even sequential access
- Aging becomes fragmented over time

Problem 3: poor locality

- inodes far from data blocks
- inodes for directory not close together poor enumeration performance e.g., "ls", "grep foo *.c"

FFS - Fast File System

→ Design FS structures and allocation polices to be "disk aware" Designed by a Berkeley research group for the BSD UNIX
