Basic Directory Operations

Unix

- → Directories implemented in file and a C runtime library provides a higher-level abstraction for reading directories
 - opendir(name)
 - readdir(DIR)
 - seekdir(DIR)
 - closedir(DIR)

Windows

- → Explicit dir operations
 - CreateDirectory(name)
 - RemoveDirectory(name)
 - FindFirstFile(pattern)
 - FindNextFile()

A Short History of Directories

Approach I: Single directory for entire system

- Put directory at known location on disk
- Directory contains hname, inumber i pairs
- If one user uses a name, no one else can
- Many ancient personal computers work this way

Approach 2: Single directory for each user

• Still clumsy, and 1s on 10,000 files is a real pain

Approach 3: Hierarchical name spaces

- Allow directory to map names to files or other directories
- File system forms a tree (or graph, if links allowed)
- Large name spaces tend to be hierarchical
 (ip addresses, domain names, scoping in programming languages, etc.)
